TPS6755
ADJUSTABLE INVERTING DC/DC CONVERTER

- 1-W Output (VCC ≥ 4.5 V)
- 2.7-V to 9-V Input Operating Range
- 78% Typical Efficiency
- 160-kHz Fixed-Frequency Current-Mode PWM Controller
- EN Input Inhibits Operation and Reduces Supply Current to 1 µA
- Output Voltage Limited to |VO| ≤ 12 V– VCC
- Soft Start
- 8-Pin SOIC and DIP Packages
- −40°C to 85°C Free-Air Temperature Range
- Pin-for-Pin Compatible with MAX755

description

The TPS6755 is an adjustable inverting dc/dc converter capable of operating from inputs as low as 2.7 V. The only external components required are an inductor, an output filter capacitor, an input filter capacitor, a reference filter capacitor, two resistors, and a Schottky rectifier. An enable input is provided to shut down the inverter when an output voltage is not needed. The typical supply current is 1.9 mA at no-load and is further reduced to 1-µA when the enable input is low.

The device features a 160-kHz current-mode pulse-width-modulation (PWM) controller with a p-channel MOSFET power switch. The gate drive uses the converter output to reduce the die area needed to realize the 0.4-Ω MOSFET. Soft start is accomplished with the addition of one small capacitor at SS. A 1.22-V reference is available for external loads up to 125 µA.

The TPS6755 is attractive for board-level dc/dc conversion in computer peripherals and in battery-powered equipment requiring high efficiency and low supply current.

Available in an 8-pin DIP or an 8-pin SOIC package, the TPS6755 operates over a free-air temperature range of −40°C to 85°C.

![Figure 1. Typical Circuit](image)

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.
The D package is also available taped and reeled (TPS6755IDR).

chip information

These chips, when properly assembled, display characteristics similar to the TPS6755. Thermal compression or ultrasonic bonding may be used on the doped aluminum bonding pads. The chips may be mounted with conductive epoxy or a gold-silicon preform.

detailed description

The following descriptions refer to the functional block diagram.

current-sense amplifier

The current-sense amplifier, which has a fixed gain of 3, amplifies the slope-compensated current-sense voltage (a summation of the voltage on the current-sense resistor and the oscillator ramp) and feeds it to the PWM comparator.

driver latch

The latch, which consists of a set/reset flip-flop and associated logic, controls the state of the power switch by turning the driver on and off. A high output from the latch turns the switch on; a low output turns it off. In normal operation the flip-flop is set high during the clock pulse, but gating keeps the latch output low until the clock pulse is over. The latch is reset when the PWM comparator output goes high.

enable (EN)

A logic low on EN puts the TPS6755 in shutdown mode. In shutdown, the output power switch, voltage reference, and other functions shut off and the supply current is reduced to 10 µA maximum. The soft-start capacitor is discharged through a 1.2-MΩ resistance and the output falls to zero volts.

error amplifier

The error amplifier is a high-gain differential amplifier used to regulate the converter output voltage. The amplifier generates an error signal, which is fed to the PWM comparator, by comparing a sample of the output voltage to the reference and amplifying the difference. The output sample is obtained from a resistive divider connected between FB and REF. FB is connected externally to the converter output, and the divider output is connected to the error-amplifier input. An 82-pF capacitor connected between COMP and GND is required to stabilize the control loop for loads greater than 100 mA.

oscillator and ramp generator

The oscillator circuit provides a 160-kHz clock to set the converter operating frequency, and a timing ramp for slope compensation. The clock waveform is a pulse, a few hundred nanoseconds in duration, that is used to limit the maximum power switch duty cycle to 95%. The timing ramp is summed with the current-sense signal at the input to the current-sense amplifier.

overcurrent comparator

The overcurrent comparator monitors the current in the power switch. The comparator trips and initiates a soft-start cycle if the power-switch current exceeds 2 A peak.

power switch

The power switch is a 0.4-Ω p-channel MOSFET with current sensing. The drain is connected to OUT and the source is connected to a current-sense resistor. The voltage across the resistor is proportional to current in the power switch and is tied to the overcurrent comparator and the current-sense amplifier. In normal operation, the power switch is turned on at the start of each clock cycle and turned off when the PWM comparator resets the drive latch.

PWM comparator

The comparator resets the drive latch and turns off the power switch whenever the slope-compensated current-sense signal from the current-sense amplifier exceeds the error signal.

reference

The 1.22-V reference is brought out on REF and can source 125-µA maximum to external loads. A 10-µF capacitor connected between REF and GND is recommended to minimize noise pickup.
SS clamp

The SS clamp circuit limits the signal level on error-amplifier output during start-up. The voltage on SS is amplified and used to override the error-amplifier output until the error-amplifier voltage rises above that output, at which point the error amplifier takes over. This prevents the input to the PWM comparator from exceeding its common-mode range (i.e., error amplifier output too high to be reached by the current ramp) by limiting the maximum voltage on the error-amplifier output during start-up.

Soft start causes the output voltage to increase to the regulation point at the controlled rate. The voltage on the charging soft-start capacitor gradually raises the clamp on the error amplifier output voltage, limiting surge currents at power up by increasing the current limit threshold on a cycle-by-cycle basis. A soft-start cycle is initiated when either the enable (EN) signal is switched high or an overcurrent fault condition triggers the discharge of the soft-start capacitor.

Figure 9

Figure 10

Figure 11

Figure 12
The TPS6755 operates in the voltage-inverting circuit, shown in Figure 15, which can generate an output. The circuit is ideal for applications that require a negative polarity voltage on the output with respect to the input ground, and for energy management systems. The TPS6755 can be placed in a shutdown mode (1-µA quiescent current) by forcing EN low.

**soft start**

The soft-start capacitor provides an orderly start-up of the converter by slowly increasing the switch current limit during power-up. The soft-start timing is controlled by the SS capacitance (see Figure 13 for the capacitance value corresponding to the desired delay time). The switch current limit is proportional to the voltage applied to SS, which is internally pulled to REF by a 1.2-MΩ resistor. SS can be externally pulled lower than REF to limit the switch current. A UVLO condition or an overcurrent condition initiates an SS cycle by discharging the SS capacitor to ground through an internal transistor. A minimum of a 10-nF capacitor must be connected to SS to current limit correctly.

**inductor selection**

The standard 10-µH inductor required by the TPS6755 must have a saturation current greater than the peak switch current at the desired maximum load. Operation over the full voltage range and current range is assured by the 10-µH inductor. To determine the required inductor saturation level, refer to the typical operating characteristics graph for peak inductor current versus load current (see Figure 8).
APPLICATION INFORMATION

output filter capacitor

A low equivalent series resistance (ESR) output filter capacitor is necessary to minimize the output-ripple voltage. An ESR of 100 mΩ limits the output ripple to 90 mV or less for output loads up to 200 mA.

rectifier

A Schottky diode or high-speed silicon rectifier should be used with a maximum continuous current rating of 1 A for operation up to full load.

output ripple filtering

A low-pass filter may be added to the converter output to reduce the output voltage ripple (see Figure 15). The LC filter has a cutoff frequency of 7.2 kHz. The inductor filter must have a low resistance to avoid large output voltage drops. The output voltage ripple is reduced to 5 mV when the LC output filter is used. FB must be connected to the output node before the connection for the low-pass filter.

adjustable output voltage

The output voltage of the TPS6755 is limited to $|V_O| \leq 12 \text{ V} - V_{CC}$ and is set by two external resistors, R4 and R5 (see Figure 15). R5 can be set to any value between 10 kΩ to 20 kΩ, and R4 is calculated using the following formula: $R_4 = \frac{|V_O|}{R_5/1.22 \text{ V}}$. These resistors form a voltage divider between FB, COMP, and REF. The converter adjusts the output such that COMP level is at GND.

printed circuit board layout

A ground plane is recommended in a printed circuit board (PCB) layout to ensure quiet operation. Attention should be given to minimizing the lengths of the switching loops. Bypass capacitors should be placed as close to the TPS6755 as possible to prevent instability and noise pickup. $V_{CC}$ and GND should be bypassed directly with a 1-µF ceramic capacitor and a large bypass capacitor (e.g. 47 µF) to maximize noise immunity. The TPS6755 should not be used with IC sockets, wire-wrap prototype boards, or other constructions that are susceptible to noise pick-up.

IMPORTANT NOTICE

Texas Instruments (TI) reserves the right to make changes to its products or to discontinue any semiconductor product or service without notice, and advises its customers to obtain the latest version of relevant information to verify, before placing orders, that the information being relied on is current.

TI warrants performance of its semiconductor products and related software to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are utilized to the extent TI deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

Certain applications using semiconductor products may involve potential risks of death, personal injury, or severe property or environmental damage ("Critical Applications").

TI SEMICONDUCTOR PRODUCTS ARE NOT DESIGNED, INTENDED, AUTHORIZED, OR WARRANTED TO BE SUITABLE FOR USE IN LIFE-SUPPORT APPLICATIONS, DEVICES OR SYSTEMS OR OTHER CRITICAL APPLICATIONS.

Inclusion of TI products in such applications is understood to be fully at the risk of the customer. Use of TI products in such applications requires the written approval of an appropriate TI officer. Questions concerning potential risk applications should be directed to TI through a local SC sales office.

In order to minimize risks associated with the customer's applications, adequate design and operating safeguards should be provided by the customer to minimize inherent or procedural hazards.

TI assumes no liability for applications assistance, customer product design, software performance, or infringement of patents or services described herein. Nor does TI warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of TI covering or relating to any combination, machine, or process in which such semiconductor products or services might be or are used.
